movq, addq
jmp, jne

Logic gates

Transistors

So far in 252...

- ISA is the interface between assembly programs and microarchitecture
- Assembly view:
 - How to program the machine, based on instructions and **processor states** (registers, memory, condition codes, etc.)?
 - Instructions are executed sequentially.
- Microarchitecture view:
 - What hardware needs to be built to run assembly programs?
 - How to run programs as fast (energy-efficient) as possible?

(Simplified) x86 Processor State

- Processor state is what's visible to assembly programs. Also known as architecture state.
- Program Registers: 16 registers.
- Condition Codes: Single-bit flags set by arithmetic or logical instructions (ZF, SF, OF)
- Program Counter: Indicates address of next instruction
- Program Status: Indicates either normal operation or error condition
- Memory
 - Byte-addressable storage array
 - Words stored in little-endian byte order

Why Have Instructions?

- Why do we need an ISA? Can we directly program the hardware?
- Simplifies interface
 - Software knows what is available
 - Hardware knows what needs to be implemented
- Abstraction protects software and hardware
 - Software can run on new machines
 - Hardware can run old software
- Alternatives: Application-Specific Integrated Circuits (ASIC)
 - No instructions, (largely) not programmable, fixed-functioned, so no instruction fetch, decoding, etc.
 - So could be implemented extremely efficiently.
 - Examples: video/audio codec, (conventional) image signal processors, (conventional) IP packet router

Today: Instruction Encoding

- How to translate assembly instructions to binary
 - Essentially how an assembler works
- Using the Y86-64 ISA: Simplified version of x86-64

How are Instructions Encoded in Binary?

- Remember that instructions are stored in memory **as bits** (just like data)
- Each instruction is fetched (according to the address specified in the PC), decoded, and executed by the CPU
- The ISA defines the format of an instruction (syntax) and its meaning (semantics)
- Idea: encode the two major fields, opcode and operand, separately in bits.
 - The OPCODE field says what the instruction does (e.g. ADD)
 - The OPERAND field(s) say where to find inputs and outputs

Y86-64 Instructions

halt

nop

cmoveXX rA, rB

irmovq V, rB

rmmovq rA, D(rB)

mrmovq D(rB), rA

OPq rA, rB

jXX Dest

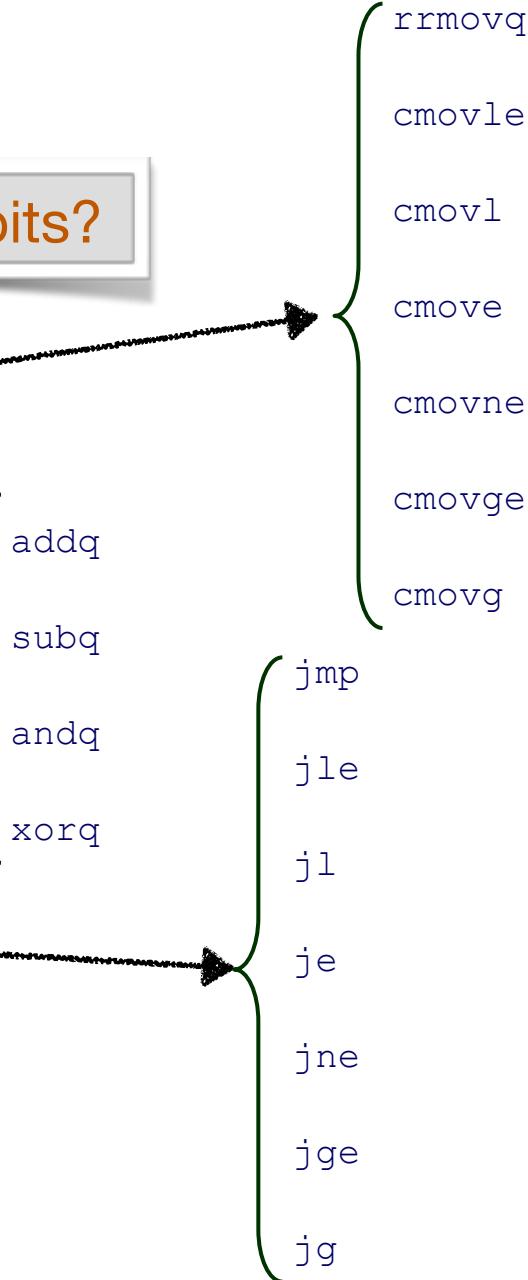

call Dest

ret

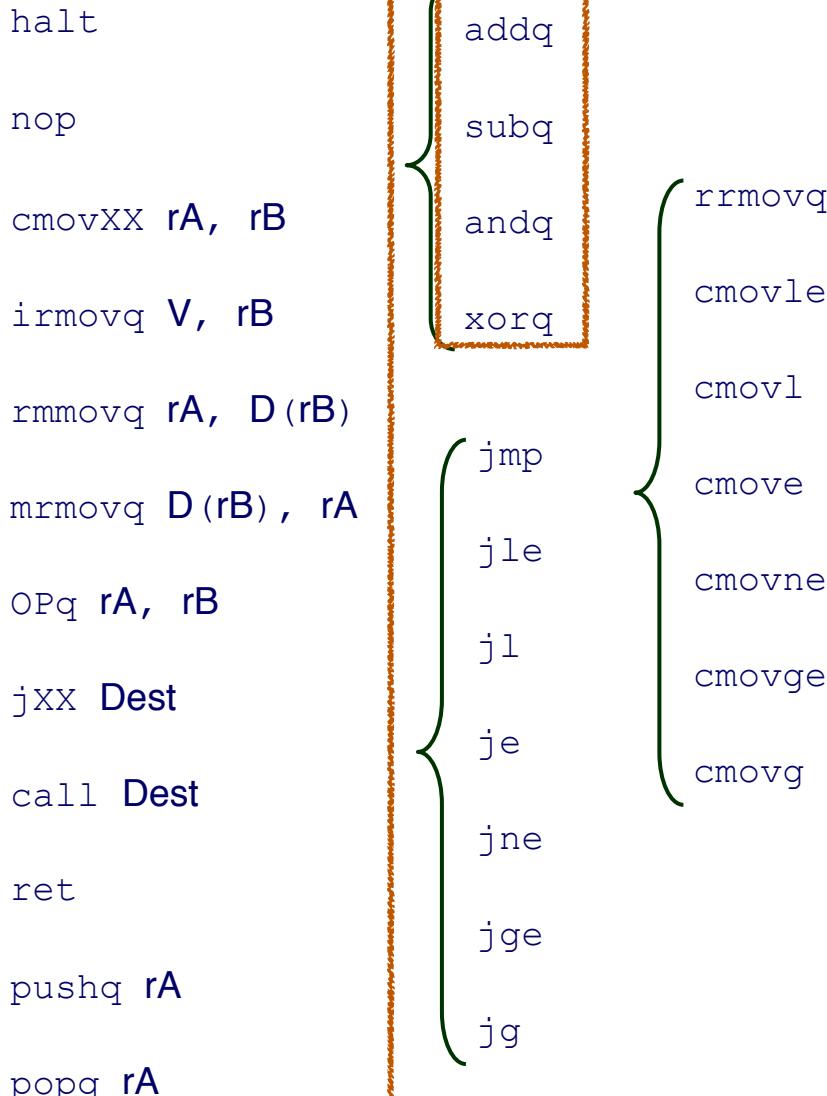

pushq rA

popq rA

How to encode them in bits?

Encoding Operands

- 27 Instructions, so need 5 bits for encoding the opcode.
- Or: group similar instructions, use one opcode for them, and then use more bits to indicate specific instructions within a group.
- E.g., 12 categories, so 4 bits
- There are four instructions within the OPq category, so additional 2 bits. Similarly, 3 more bits for jXX and cmovXX, respectively.
- Which one is better???

Encoding Operands

Byte	0	1	2	3	4	5	6	7	8	9
halt	0	0								
nop	1	0								
cmoveXX rA, rB	2	fn								
irmovq V, rB	3	0								
rmmovq rA, D(rB)	4	0								
mrmovq D(rB), rA	5	0								
OPq rA, rB	6	fn								
jXX Dest	7	fn								
call Dest	8	0								
ret	9	0								
pushq rA	A	0								
popq rA	B	0								

• Design decision chosen by the textbook authors (don't have to be this way!)

- Use 4 bits to encode the instruction category
- Another 4 bits to encode the specific instructions within a category
- So 1 byte for encoding opcode.
- Is this better than the alternative of using 5 bits without classifying instructions?
- Trade-offs.

Encoding Registers

Each register has 4-bit ID

- Same encoding as in x86-64
- Register ID 15 (0xF) indicates “no register”

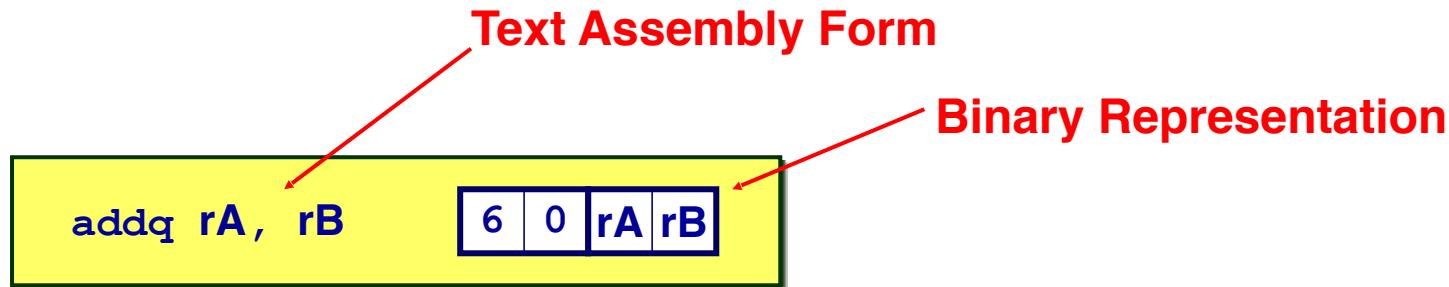

%rax	0	%r8	8
%rcx	1	%r9	9
%rdx	2	%r10	A
%rbx	3	%r11	B
%rsp	4	%r12	C
%rbp	5	%r13	D
%rsi	6	%r14	E
%rdi	7	No Register	F

Encoding Registers

Byte	0	1	2	3	4	5	6	7	8	9
halt	0	0								
nop	1	0								
cmoveXX rA, rB	2	fn	rA	rB						
irmovq V, rB	3	0	F	rB						
rmmovq rA, D(rB)	4	0	rA	rB						
mrmovq D(rB), rA	5	0	rA	rB						
OPq rA, rB	6	fn	rA	rB						
jXX Dest	7	fn								
call Dest	8	0								
ret	9	0								
pushq rA	A	0	rA	F						
popq rA	B	0	rA	F						

Instruction Example

Addition Instruction

- Add value in register rA to that in register rB
 - Store result in register rB
- Set condition codes based on result
- e.g., addq %rax, %rsi Encoding: 60 06
- Two-byte encoding
 - First indicates instruction type
 - Second gives source and destination registers

Arithmetic and Logical Operations

Add

`addq rA, rB`

6	0	rA	rB
---	---	----	----

Subtract (rA from rB)

`subq rA, rB`

6	1	rA	rB
---	---	----	----

- Referred to generically as “OPq”
- Encodings differ only by “function code”
 - Low-order 4 bytes in first instruction word
- Set condition codes as side effect

And

`andq rA, rB`

6	2	rA	rB
---	---	----	----

Exclusive-Or

`xorq rA, rB`

6	3	rA	rB
---	---	----	----

Move Instructions

Byte 0 1 2 3 4 5 6 7 8 9

halt

0	0
---	---

nop

1	0
---	---

cmovXX rA, rB

2	fn	rA	rB
---	----	----	----

The instruction length limits the immediate value and displacement.

irmovq V, rB

3	0	F	rB		irmovq \$0xabcd, %rdx	
---	---	---	----	--	-----------------------	--

rmmovq rA, D(rB)

4	0	rA	rB		rmmovq %rsi, 0x41c(%rsp)	
---	---	----	----	--	--------------------------	--

mrmovq D(rB), rA

5	0	rA	rB		mrmovq -12(%rbp), %rcx	
---	---	----	----	--	------------------------	--

OPq rA, rB

6	fn	rA	rB
---	----	----	----

jXX Dest

7	fn
---	----

call Dest

8	0
---	---

ret

9	0
---	---

pushq rA

A	0	rA	F
---	---	----	---

popq rA

B	0	rA	F
---	---	----	---

Move Instruction Examples

Y86-64

```
irmovq $0xabcd, %rdx
```

Encoding: 30 82 cd ab 00 00 00 00 00 00

```
rrmovq %rsp, %rbx
```

Encoding: 20 43

```
mrmovq -12(%rbp),%rcx
```

Encoding: 50 15 f4 ff ff ff ff ff ff ff ff

```
rmmovq %rsi,0x41c(%rsp)
```

Encoding: 40 64 1c 04 00 00 00 00 00 00

Jump/Call Instructions

Byte

halt

0	0
---	---

nop

1	0
---	---

cmoveXX rA, rB

2	fn	rA	rB
---	----	----	----

The assembly would assume a start address of the program, and then calculates the address of each instruction.

irmovq V, rB

3	0	F	rB	V
---	---	---	----	---

rmmovq rA, D(rB)

4	0	rA	rB	D
---	---	----	----	---

mrmovq D(rB), rA

5	0	rA	rB	D
---	---	----	----	---

OPq rA, rB

6	fn	rA	rB
---	----	----	----

jXX Dest

7	fn	jle .L4	(all the target address)
---	----	---------	--------------------------

call Dest

8	0	Dest	call foo	(the start address of the callee)
---	---	------	----------	-----------------------------------

ret

9	0
---	---

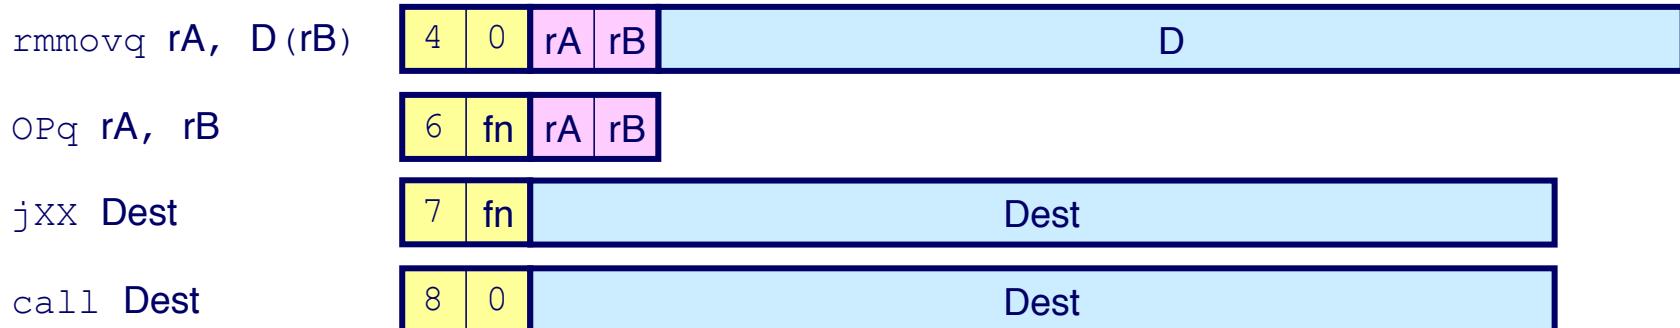

pushq rA

A	0	rA	F
---	---	----	---

popq rA

B	0	rA	F
---	---	----	---

How Does An Assembler Work?

0x100	<foo>	<code>rmmovq %rsi,0x41c(%rsp)</code>	40 64 1c 04 00 00 00 00 00 00
	
0x100 + the lengths of all instructions in-between		<code>ret</code>	90
		<code>addq %rax,%rsi</code>	60 06
		<code>call <foo></code>	80 00 01 00 00 00 00 00 00 00
		<code>jmp .L0</code>	70 00 02 00 00 00 00 00 00 00
	
0x200	.L0	<code>irmovq \$0xabcd, %rdx</code>	30 f2 cd ab 00 00 00 00 00 00

How Does An Assembler Work?

- The assembler is a program that translates assembly code to binary code
- The OS tells the assembler the start address of the code (sort of...)
- Translate the assembly program line by line
- Need to build a “label map” that maps each label to its address

0x100	<foo>	rmmovq %rsi,0x41c(%rsp)	40 64 1c 04 00 00 00 00 00 00
		...	
0x100 + the lengths of all instructions in-between		ret	90
		addq %rax,%rsi	60 06
		call <foo>	80 00 01 00 00 00 00 00 00 00
		jmp .L0	70 00 02 00 00 00 00 00 00 00
		...	
0x200	.L0	irmovq \$0xabcd, %rdx	30 f2 cd ab 00 00 00 00 00 00

Jump Instructions

Jump Unconditionally

jmp Dest 7 | 0 Dest

Jump When Less or Equal

jle Dest 7 | 1 Dest

Jump When Less

jl Dest 7 | 2 Dest

Jump When Equal

je Dest 7 | 3 Dest

Jump When Not Equal

jne Dest 7 | 4 Dest

Jump When Greater or Equal

jge Dest 7 | 5 Dest

Jump When Greater

jg Dest 7 | 6 Dest

Subroutine Call and Return

`call Dest`

8	0
---	---

Dest

- Push address of next instruction onto stack
- Start executing instructions at Dest
- Like x86-64

`ret`

9	0
---	---

- Pop value from stack
- Use as address for next instruction
- Like x86-64

One More Complication...

Byte	0	1	2	3	4	5	6	7	8	9
jxx Dest	7	fn	Dest (essentially the target address)						jle .L4	
call Dest	8	0	Dest (essentially the start address of the callee)						call foo	

- The instruction length limits how far you can jump/call functions. What if the jump target has a very long address that can't fit in 8 bytes?
 - Or if we can use only say 4 bytes for the target address?
- One alternative: use a super long instruction encoding format.
 - Simple to encode, but space inefficient (waste bits for jumps to short addr.)
- Another alternative: encode the relative address, not the absolute address
 - E.g., encode (.L4 - current address) in Dest

Using Relative Addresses for Jumps

- What if the ISA encoding uses relative address for jump and call?
- If we use relative address, the exact start address of the code doesn't matter. Why?
- This code is called Position-Independent Code (PIC)

0x100	<foo>	rmmovq %rsi,0x41c(%rsp)	40 64 1c 04 00 00 00 00 00 00
relative addr: -0x80		...	
0x180		ret	90
0x185		addq %rax,%rsi	60 06
0x200	.L0	call <foo>	80 00 00 00 11 11 11 11 11
		jmp .L0	70 7B 00 00 00 00 00 00 00 00
		...	
		irmovq \$0xabcd, %rdx	30 f2 cd ab 00 00 00 00 00 00

Miscellaneous Instructions

- Don't do anything

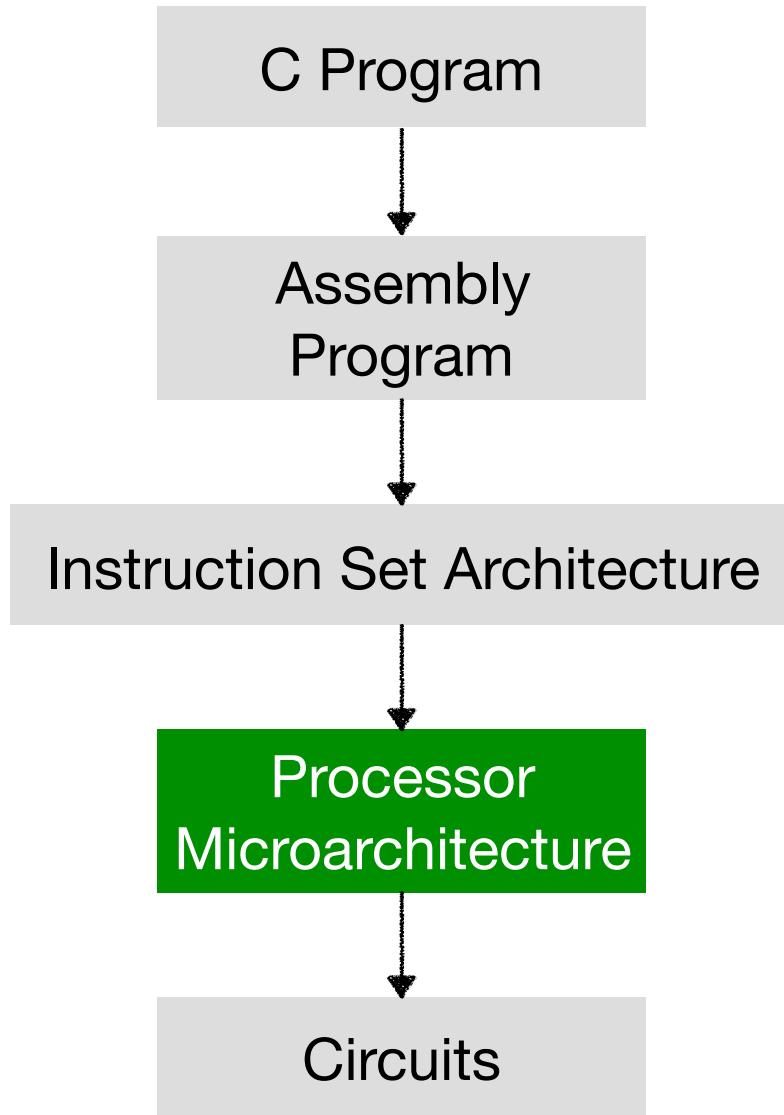

- Stop executing instructions
- Usually can't be executed in the user mode, only by the OS
- Encoding ensures that program hitting memory initialized to zero will halt

Variable Length Instructions

- X86 (and Y86) is a variable length ISA (1 to 15 bytes), where different instructions have different lengths.
- There are fixed length ISAs: all instructions have the same length
 - ARM's ISA for micro-controllers have a 4-bit ISA. Very Long Instruction Word (VLIW) ISAs have instructions that are hundreds of bytes long.
 - Or you can have a combination of both: e.g., 16-bit ISA with 32-bit extensions (e.g, ARM Thumb-extension).
- Advantages of variable length ISAs
 - More compact. Some instructions do not need that many bits. (Actually what's the optimal way of encoding instructions in a variable length ISA?)
 - Can have arbitrary number of instructions: easy to add new inst.
- What is the down side?
 - Fetch and decode are harder to implement. More on this later.
- A good writeup showing some of the complexity involved:
<http://www.c-jump.com/CIS77/CPU/x86/lecture.html>

So far in 252...

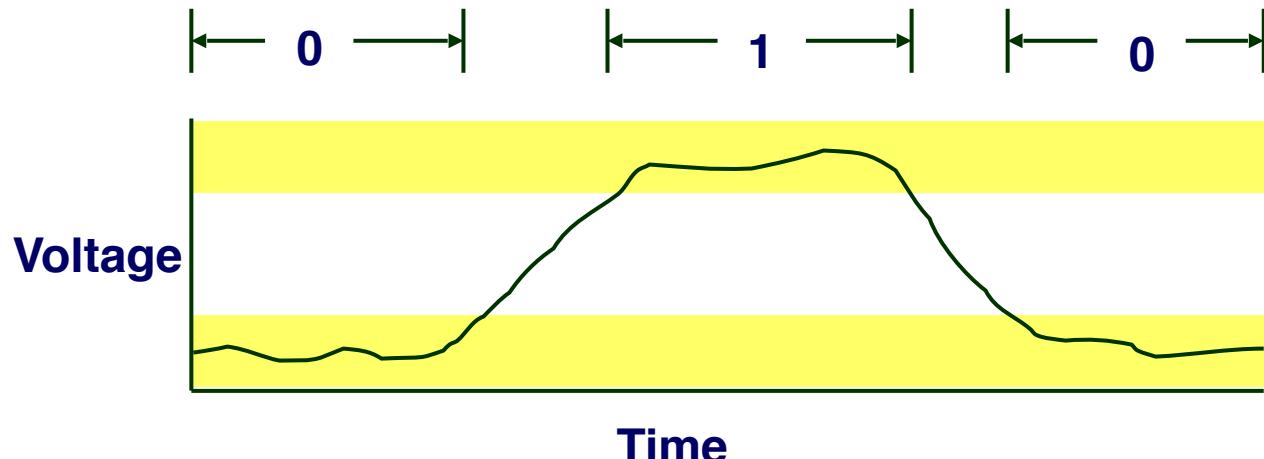

Today: Circuits Basics

- Basics
- Circuits for computations
- Circuits for storing data

Overview of Circuit-Level Design

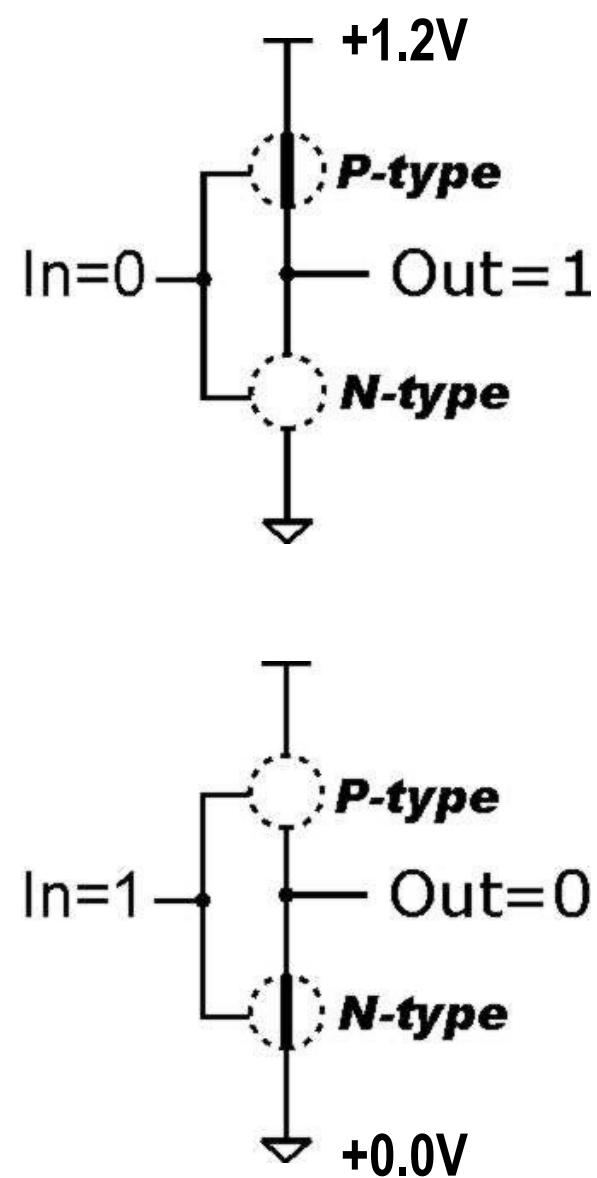

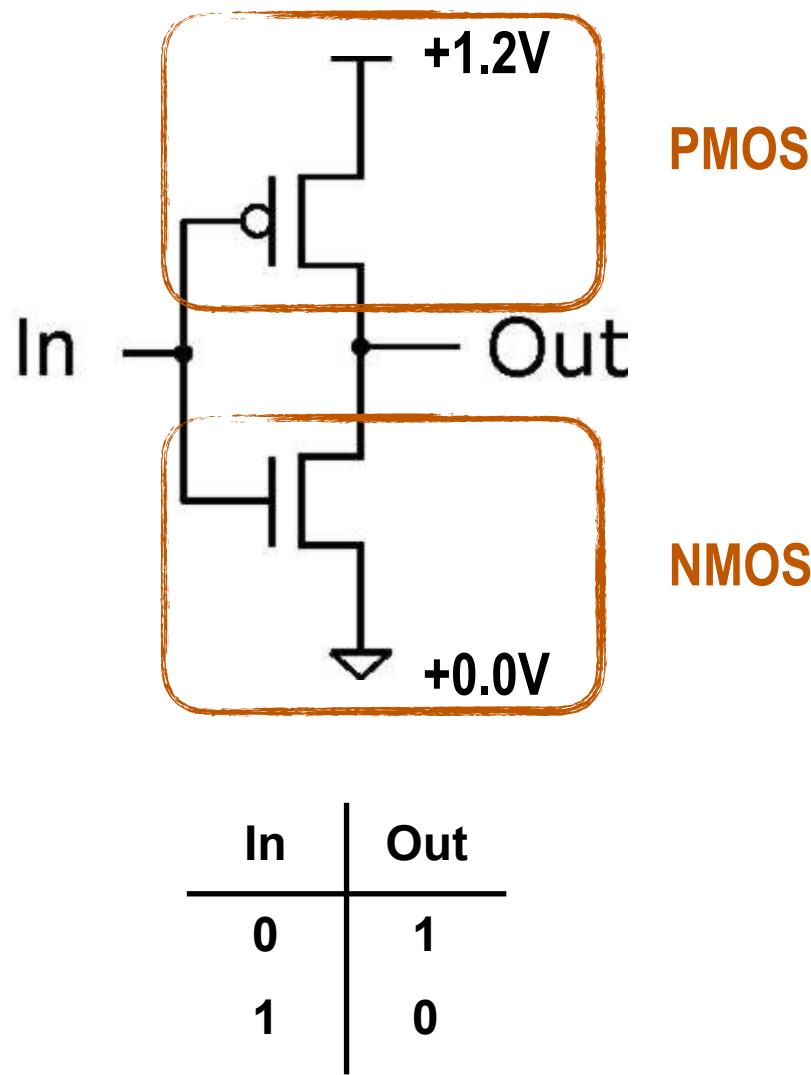

- Fundamental Hardware Requirements
 - Communication: How to get values from one place to another. Mainly three electrical **wires**.
 - Computation: **transistors**. Combinational logic.
 - Storage: **transistors**. Sequential logic.
- Circuit design is often abstracted as **logic design**

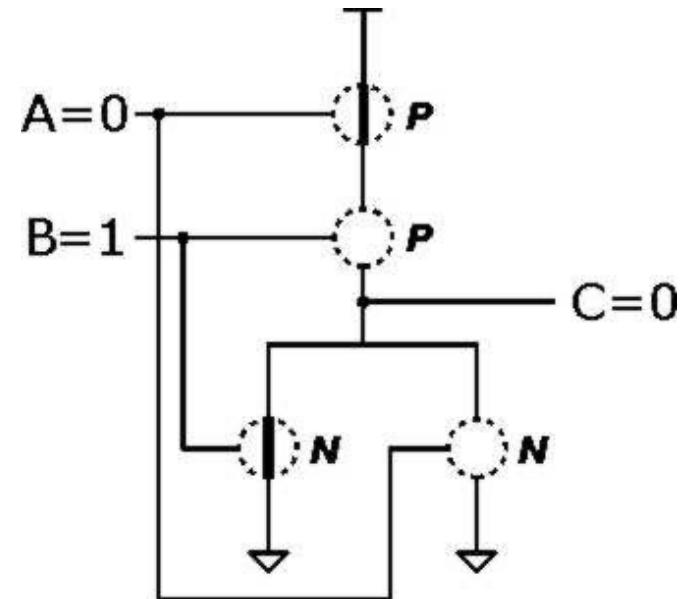

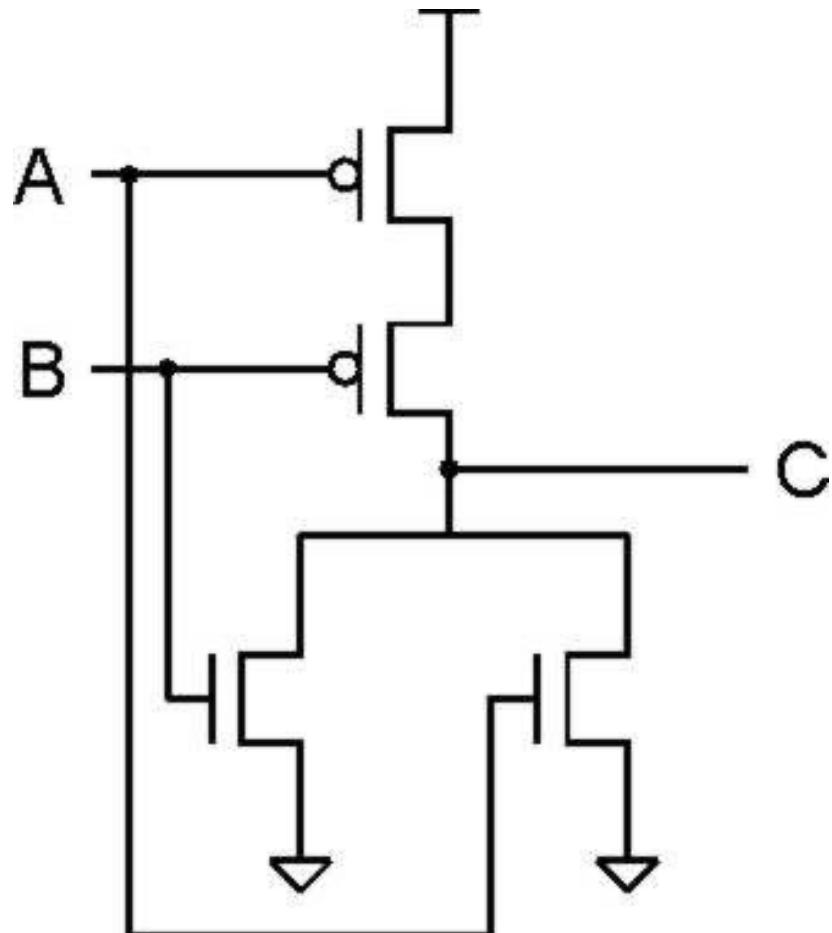

Today: Circuits Basics

- Transistors
- Circuits for computations
- Circuits for storing data

Inverter (NOT Gate)

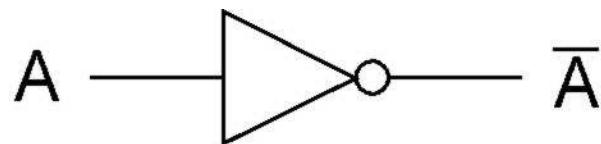

NOR Gate (NOT + OR)

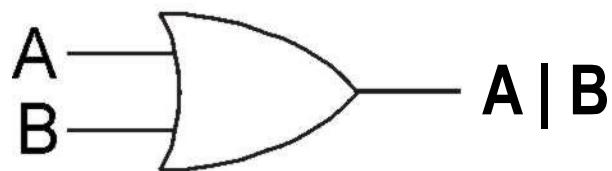

A	B	C
0	0	1
0	1	0
1	0	0
1	1	0

Note: Serial structure on top, parallel on bottom.

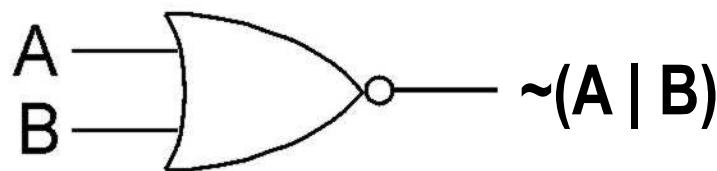

Basic Logic Gates

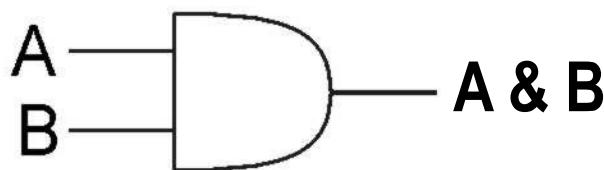

NOT

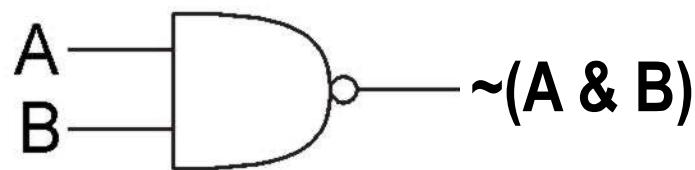

OR

NOR

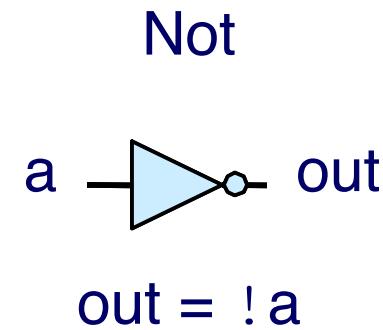

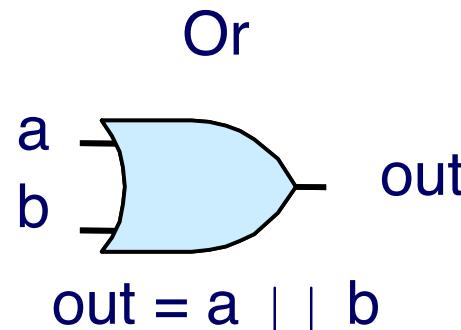

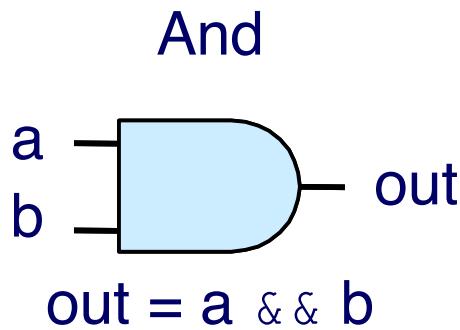

AND

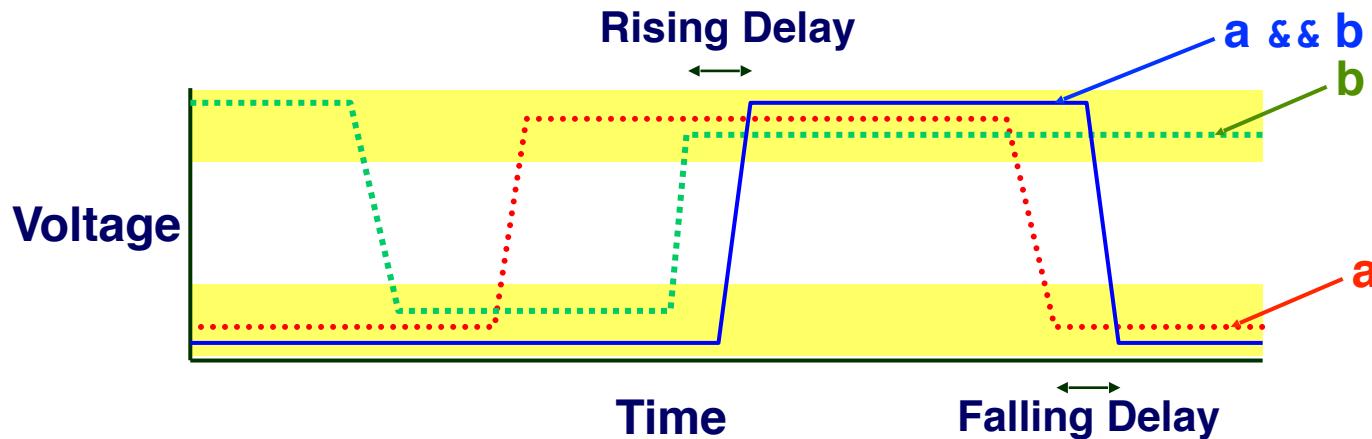

NAND

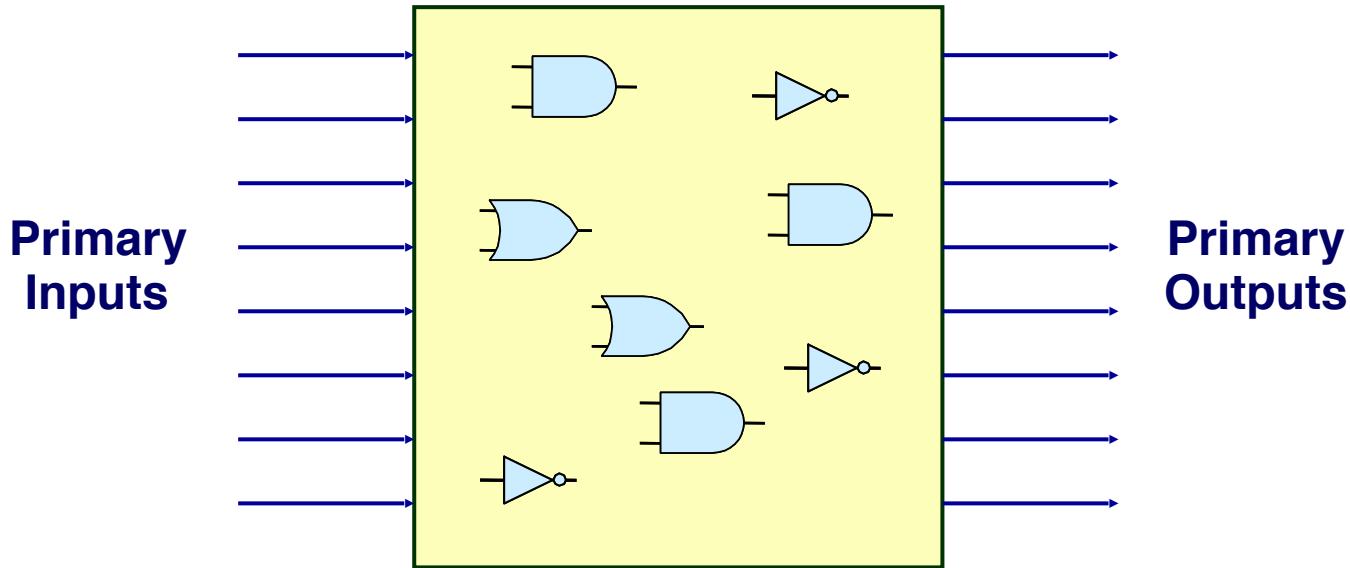

Computing with Logic Gates

- Outputs are Boolean functions of inputs
- Respond continuously to changes in inputs with some small delay
- Different gates have different delays (b/c different transistor combinations)

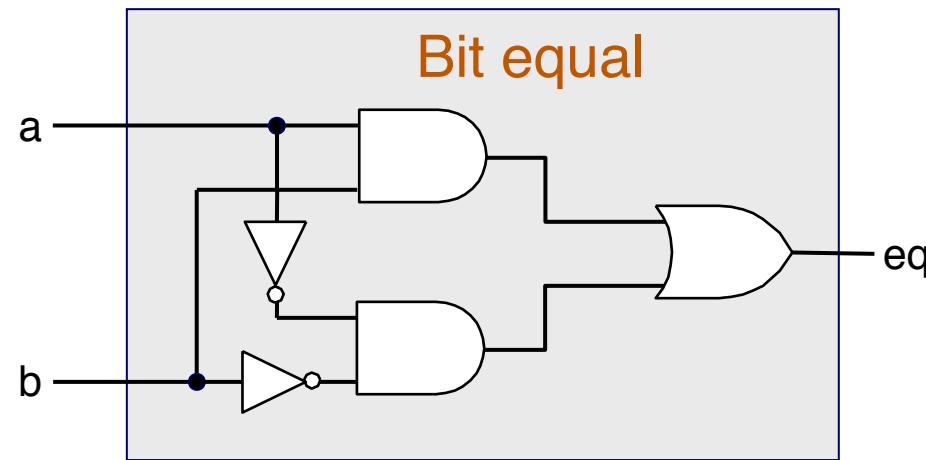

Combinational Circuits

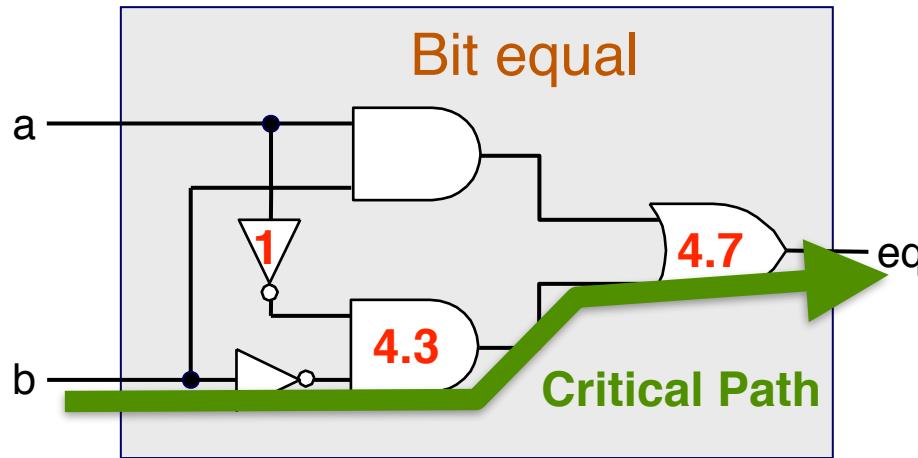

- A Network of Logic Gates
 - Continuously responds to changes on primary inputs
 - Primary outputs become (**after some delay**) Boolean functions of primary inputs

Bit Equality

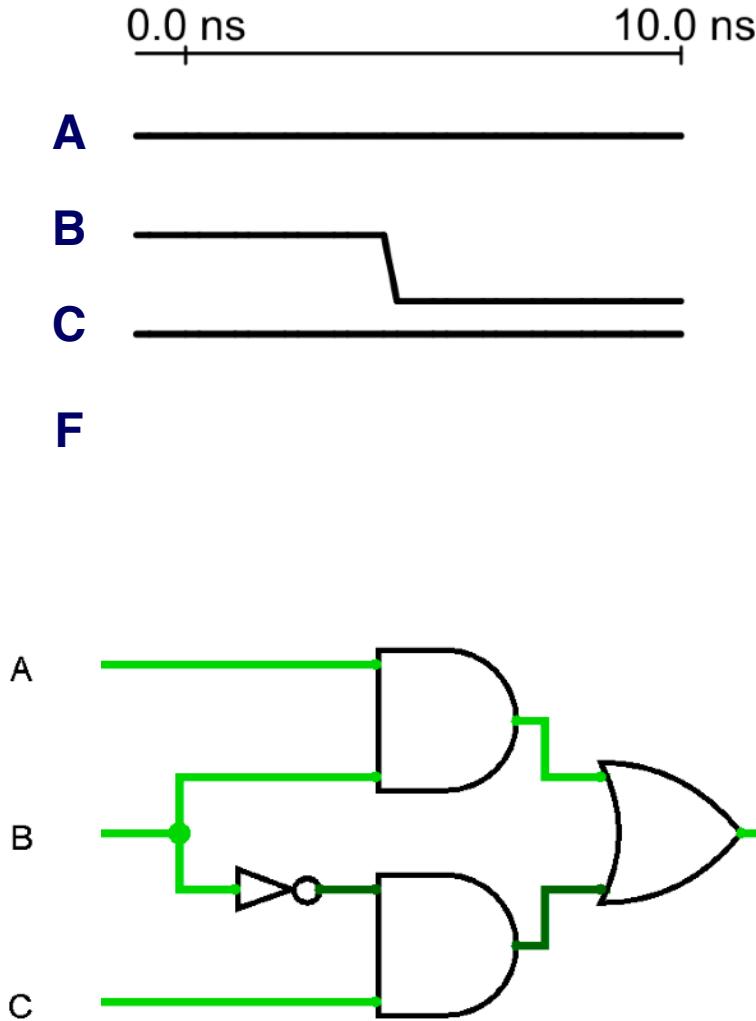

Delay of Bit Equal Circuit

- What's the delay of this bit equal circuit?
 - Assuming 1-input NOT takes 1 unit of time, 2-input AND takes 4.3, and 2-input OR takes 4.7
- The delay of a circuit is determined by its “critical path”
 - The path between an input and the output that has the maximum delay
 - Estimating the critical path delay is called static timing analysis

Glitch/Hazard

- A glitch is an unnecessary signal transition without functionality.
- Why is it bad? When transistors switch they consume power, but the power consumed during a glitch is a waste.
- Without care, glitch power dissipation is 20%-70% of total power dissipation.

64-bit Equality
